

How can we link domain name of one organization with hosting server of another organization.

Domain name is like www.cppcourses.com

hosting server is the server where you have placed your html files or your web content.

For linking domain name with hosting service you need nameservers which you can get from web hosting service provider.

Example of name servers are

ns1.dreamhost.com

ns2.dreamhost.com

You can update these name servers in domain name service provider control panel.

Then you have to update your wireless network adapter dns ip address as 8.8.8.8 which is dns ip address of google.com

Following are the steps to do that

- To change the DNS address on Windows 11, open Settings > Network & internet and select Ethernet or Wi-Fi.
- Then open the “DNS server assignment” settings and change the DNS address.

Set DNS address as 8.8.8.8

and now open your domain name in web browser and you will be able to see your website.
