

This is a Tutorial on how hacking can be done through Trojan Horses.

Trojan Horse is a software that has two parts: server and client.

Trojan Horse server is kept on victim machine or the person whose machine has to be hacked.

For example:

X is a Hacker and Y is a victim so X will place a Trojan Horse software on Y machine and will gain access to machine of Y.

Now after gaining access to Y's machine X can control the system or machine of Y through his own machine.

X who is a hacker can set a keylogger on Y Machine through Trojan Horse and can get all the keys typed by Y.

This is the way a Trojan Horse Works.
